Abstract-- The objective of this experimental study is to discuss the thermal performance of car radiator using Al₂O₃-nanofluid in temperature ranges from (40-75°C) under different fractions of nanoparticles from 0.5, 1, 1.5% by volume. In this study, the heat transfer with water based nano fluids was experimentally compared to that of pure water as coolant in an automobile radiator. By varying the amount of Al₂O₃ nano particles blended with base fluid water, three different concentrations of nano-fluid 0.5%, 1%, 1.5% (by vol.) were obtained. The size of nanoparticle used was 100 nm. Liquid flow rate has been changed in the range of 50 lph to 200 lph and air velocity in the range of 3.8 m/s to 6.2 m/s. The fluid inlet temperature was varying from 40°C to 75°C to find the optimum inlet condition. Results demonstrate that increasing coolant flow rate can improve the heat transfer performance. Also increasing the air flow rate improves the heat transfer rate. The rate of heat transfer enhancement was found 19% to 42% in comparison with pure water.

Key Words - NanoFluid, Radiator, Flow Rate, Cooling Performance, Heat Transfer enhancement.

I. INTRODUCTION
Modern automotive internal combustion engines generate a huge amount of heat. This heat is created when the gasoline and air mixture is ignited in the combustion chamber. This explosion causes the piston to be forced down inside the engine, levering the connecting rods, and turning the crankshaft, creating power. Metal temperatures around the combustion chamber can exceed 538°C. In order to prevent the overheating of the engine oil, cylinder walls, pistons, valves, and other components by these extreme temperatures, it is necessary to effectively dispose of the heat. Approximately 1/3 of the heat in combustion is converted into power to drive the vehicle and its accessories. Another 1/3 of the heat is carried off into the atmosphere through the exhaust system. The remaining 1/3 must be removed from the engine by the cooling system. The use of nanofluids has the potential to improve the engine cooling rates. These improvements can be used to remove engine heat with a reduced size cooling system. Smaller cooling system leads to use of smaller and lighter radiators which in turn will lead to better performance and increased efficiency. Alternatively, improved cooling rates can be used to remove more heat from higher horsepower engines with same size of cooling system.

V.L.Bhimani et.al. [1] experimentally investigated forced convective heat transfer in a water based nanofluid. Five different concentrations of nanofluids in the range of 0.1-1 vol. % have been used with flow rate in the range of 90-120 lit./min. The result shows that heat transfer enhancement of 40-45% compared to pure water at the concentration of 1% vol.

Gaurav Sharma et al. [2] Experimentally investigated the thermal conductivity and viscosity of Al₂O₃-engine nano-coolant. For 0.5% vol. concentration of Al₂O₃ nanofluid at 40°C The maximum improved thermal conductivity is 5.7% and the enhancement in viscosity is 124%.

Adnan M. Hussein et al. [3] experimentally investigated the friction factor and forced convection heat transfer enhancement using SiO₂ nanoparticles suspended into water. Four different concentrations of nanofluids in the range of 1 to 4 % (Vol.) with changed flow rate from 1 to 5 lpm have been used. The maximum value of friction factor was increased to 22% and a highest value of the heat transfer coefficient enhances up to 40% for SiO₂ nanoparticles with 4% volume concentration.

Rahul A.Bhogare et.al. [4] illustrated a review on application and challenges of nano-fluids as coolant in automobile radiator. Nanofluids have great potential to improve automotive and heavy – duty engine cooling rates by increasing the efficiency, lowering the weight and reducing the complexity of thermal management.

Chavan D.K. et.al. [5] illustrated the study, analysis and design of automobile radiator proposed with CAD.
drawing and geometrical model of the fan. He investigated that velocity increases with the increase in rpm of radiator fan. So he concluded that for optimum efficiency eliminates corners and develop radiator of circular shape.

Deepak Chintakayala et. al. [6] studied the cooling effect by using a nanofluid as a coolant in a radiator and is analyzed for evaluating the fluid flow and heat transfer characteristics. This study is analyzed by using a CFD software FLUENT. It is clearly observed that loss in temperature for conventional coolant is 17°C and for nanofluid as coolant it is 20°C. From his study he concluded that the rate of heat transfer is better when nanofluid (Al₂O₃ + water) is used as coolant than conventional coolant.

Navid Bozorgan et.al.[7] numerically investigated the use of CuO-water nanofluid as a coolant in a radiator at Chevrolet suburban diesel engine with a given heat exchanger capacity. The results showed that for CuO-water nanofluid at 2 % volume concentration circulating through the flat tubes with Re -6000 while the automotive speed is 70 km/hr , the overall heat transfer coefficient and pumping power are approximately 10 % and 23.8 % more than that of base fluid for given conditions.

Paresh Machhar et.al. [8] experimentally analyzed the heat transfer enhancement of automobile radiator with TiO₂ /water nanofluid. Five different concentrations of nanofluids in the range of 0.1-1 volume % will be prepared by the addition of TiO₂ nanoparticles into the water. He observed from the investigation that the application of nanofluid with low concentration can enhance heat transfer efficiency up to 45 % in comparison with pure water.

Ravikanth S.Vajjha et.al.[9] investigated a three dimensional laminar flow and heat transfer with two different nanofluids Al₂O₃ and CuO nanoparticle in an ethylene glycol and water mixture circulating through the flat tubes of an automobile radiator. The numerical results showed at a Reynolds number of 2000, the percentage increase in the average heat transfer coefficient over the base fluid for a 10% Al₂O₃ nanofluid was 94 % and that for a 6 % CuO nanofluid was 89 %.The average skin friction coefficient for a 6% CuO nanofluid in the fully developed region is about 2.75 times in comparison to that of the base fluid at a constant inlet velocity of 0.3952 m/s.

II. NANOFLUID PREPARATION

In this experimentation a two-step procedure was used for preparing the nanofluid. A measured quantity of nanoparticle was taken and mixed thoroughly in the water. Mechanical stirrer was used to mix it uniformly. It was kept in the sonicator and subjected to vibrations so as to reduce to problem of agglomeration. Nanofluid was kept still for two days to check for sedimentation. Even after two days there was no appreciable sedimentation and the important fact is that the moment it was stirred again it turned into a uniform fluid with evenly suspended nanoparticles in it.

III. ESTIMATION OF NANOFLUID PROPERTIES

By assuming that the nanoparticles are well dispersed within the base fluid, i.e. the particle concentration can be considered uniform throughout the system; the effective physical properties of the studied mixtures can be evaluated using some classical formulas as usually used for two phase fluids. These relations have been used to predict nanofluid physical properties like density, specific heat, viscosity and thermal conductivity at different temperatures and concentrations. In this paper, the following correlations were used to calculate the physical properties of nanofluid.

\[ \rho_{nf} = (1 - \phi)\rho_f + \phi \rho_p \]  
\[ C_{p nf} = \frac{(1 - \phi)(\rho_c p_f)_{f} + \phi (\rho_c p_f)_{p}}{\rho_{nf}} \]  
\[ \nu = f (1 + 2.5 \phi) \]  
\[ \frac{k_{nf}}{k_f} = \frac{k_p + 2k_f + 2(k_p \rho_f \phi_{eff})}{k_f - 2(k_p \rho_f \phi_{eff})} \]

In the above equations, the subscripts “p”, “f” and “nf” refer to the particles, water and nanofluid respectively. The characteristics of water and Al₂O₃ nanoparticles at room temperature are summarized in Table 1.

IV. EXPERIMENTAL SETUP AND PROCEDURE

This experimental setup includes a reservoir in the form of plastic tank, electrical heater, a centrifugal pump, a flow meter, flow control valves, fan, D.C power supply; ten thermocouples type T for temperature measurement, and heat exchanger (automobile radiator). The fluid flows through plastic tubes (0.5 inch) by a centrifugal pump (1800 rpm) from the tank to the radiator. The total volume of the circulating fluid is (5 liters) and constant in all the experimental steps. An electrical heater (2000W) is placed inside a plastic storage tank (20 cm height and 18 cm diameter) which represent the engine. The heater is used to heat the working fluid. A voltage regular (0-220 V) is provided to maintain inlet fluid temperature from 40 °C to 75°C. A rotameter (0- 500 lph) and two valves used to measure and control the flow rate of the fluid. Two thermocouples (copper – constantan) types T have been fixed on the flow line for recording the inlet and outlet fluid temperatures. Eight thermocouples type T have been fixed to the radiator surface to ensure more of surface area temperature measurement. Very small thickness and high thermal conductivity of the copper flat tubes caused to make the inside temperature of the tube with the outside one are equated. A handheld (-40°C to 1000°C ) digital temperature indicator with the accuracy of ± (0.1 °C) used to read all the temperatures from thermocouples. The calibration of thermocouples carried out by using a constant temperature water bath and their accuracy estimated to be 0.15°C. The car radiator has louvered fin and 32 flat vertical copper tubes with flat cross sectional area. The distances among the tube rows filled with thin perpendicular copper fins. For the air side, an axial force fan with three stage velocities (3.8 m/s, 4.9 m/s and 6.2 m/s) was installed close and face to face to the radiator. The D.C power supply used to turn the axial fan instead of a car battery.

V. EXPERIMENTAL DATA ANALYSIS

According to Newton’s cooling law the following procedure followed to obtain heat transfer coefficient.
RESULTS AND DISCUSSION

The effect of nanofluid concentration on amount of heat transferred from car radiator at constant coolant flow rate and constant air flow rate is shown in Fig.3 and Fig.4. From Fig.3 and Fig.4, it is evident that addition of nanofluid concentration from 0.5% to 1.5% enhances the rate of heat transfer. This may be due to the fact that increased thermal conductivity due to the addition of nano particles in the base fluid water. It is observed that 19% to 42% heat transfer enhancement is attained with the addition of nanofluid.

And heat transfer rate calculated by

\[ Q = m \cdot C_p \cdot \Delta T \]

\[ m = \text{density} \cdot v \]

\[ V = \text{LPH} \cdot 0.001/3600 \]

\[ m = \text{mass flow rate of coolant Kg/s, v-volume flow rate(m^3/s)} \]

The heat transfer coefficient can be evaluated by collecting eq. (5) and (8)

\[ h = \frac{m \cdot C_p \cdot (T_{in} - T_{out})}{A \cdot (T_b - T_w)} \]

VI. RESULTS AND DISCUSSION

The heat transfer enhancement in car radiator is experimentally investigated by using Al₂O₃ nanofluid mixed with water. The concentrations of nanofluids 0.5%, 1% and 1.5% of Al₂O₃ were used in this experiment. While the flow rate was varied from 50 lph to 200 lph and the air flow rate from 3.8 m/s to 6.2 m/s. The results obtained from this experimentation were discussed below.
The effect nano fluid concentration on the amount of heat transferred from the car radiator for varying coolant flow rate with constant air flow rate was shown in Fig.5 and Fig.6. An increase in heat transfer is found for increase in coolant flow rate. Also as the nanofluid concentration increases the rate of heat transfer is also found to be increased.

The effect nano fluid concentration on the amount of heat transferred from the car radiator for varying air flow rate with constant coolant flow rate was shown in Fig.7 and Fig.8. An increase in heat transfer rate was found for increase in air flow rate. Also as the nanofluid concentration increases the rate of heat transfer is also found to be increased. Heat transfer coefficient increases as the cooling air flow increases at constant coolant flow rate.

**CONCLUSION**

In this experimental research work, the total heat transfer rate from an automotive radiator is determined using two working fluids: water and water based nanofluid (Al$_2$O$_3$) at three different concentrations 0.5%, 1% and 1.5% on volume basis. From the experimental work, the following conclusions were made.

1) 19% rate of heat transfer is increased in car radiator by addition of 0.5% Al$_2$O$_3$ nano powder of 100nm size in pure water at constant coolant flow rate of 200 lph and constant air flow rate of 6.2 m/s.
2) 33% rate of heat transfer is increased in car radiator by addition of 1% Al$_2$O$_3$ nano powder of 100nm size in pure water at constant coolant flow rate of 200 lph and constant air flow rate of 6.2 m/s.
3) 42% rate of heat transfer is increased in car radiator by addition of 1.5% Al$_2$O$_3$ nano powder of 100nm size in pure water at constant coolant flow rate of 200 lph and constant air flow rate of 6.2 m/s.
4) Addition of 0.5% to 1.5% Al$_2$O$_3$ nanopowder in pure water gives 14% to 42% heat transfer enhancement than pure water.
5) Addition of 0.5% to 1.5% Al$_2$O$_3$ nanopowder in pure water gives 15% to 47% enhancement in heat transfer coefficient than pure water.
6) Rate of heat transfer increase as the coolant flow rate increases at constant air flow rate
7) Rate of heat transfer increase as the cooling air flow increases at constant coolant flow rate
